

Plain: Each day in March-April 2014, aircraft and ships searched boxes on the sea for floating debris. We moved debris from each possible impact point with ocean currents and wind and counted the days on which it was inside a box. Colour shows the chance that nobody saw the debris. Low values mean the search argues against an impact there. The daily detection chance was not published; we used the CSIRO assumption.

Technical: 387 GA/AMSA ArcGIS polygons D11-D52 (grade A geometry, no POD); POD per box-day 1.0 / 0.15 on poor days (CSIRO 2016 Part I p.23, 2017 Part IV pp.1-2), averaged over parcels. Drift: GlobCurrent 0 m daily + 0.5 % of CMEMS L4 hourly 10 m wind (product-relative, as the drift module; 1.2 % and 2.5 % sensitivities), K 100 m2/s, 256 parcels per 0.25 deg cell. Panel b weights: run J, 00:19 data held out, q=1/3 (C2 silent), x pre-registered acoustic likelihood (core). Physics not calibrated.
