
Simple: New drift run at 66 points along the 7th arc. Each latitude has a point on the most likely impact track and points 50 NM either side. The error bars are 2 standard deviations of Monte Carlo noise. The northern part of the flight-path PDF is made from few flight paths, so its shape north of 33° S is not reliable.
Technical: Drift module (aus160 configuration, 15–160 E, d51d80a binary cbe08758), 1e6 particles per point at 33–40° S in 0.5° steps, 3e5 at 26–32° S in 1° steps, 50 km recovery bandwidth, window 8 Mar 2014–30 Jun 2016, 3 object classes, 4 ocean-error realisations, mixture of GLORYS12+ERA5 and GlobCurrent+ERA5 (equal weight). Detection levels relative to find coasts: option B 1/0.3/0.05 (city+inner regional/outer regional/remote), option C 0.3/0.1/0.02, populated only 1/0/0, all pre-registered except populated only (Pete's 15 Oct ruling), log-normal SD 1 per level. Panel a: track points; 2-sigma from split halves. Panel b: run J D0 (q=1/3, C2 silent) impact histogram weighted by inverse-distance (6 nearest points) log-likelihood; 0.35% of flight-path mass lies outside 25.4–40.4° S. Labelled sensitivity.
