
Simple words: This chart uses the satellite data to 00:11 and our model of the last part of the flight. It adds a second set of flight paths that goes more to the north. We add the two sets by a fixed rule. The rule does not change the answer; it only makes the north less noisy. The physics of the last part of the flight is not yet calibrated.

Technical: source posterior = core run J, waypoints stratum (24 seeds) + run-J northern supplement (16 seeds, all rows, multiple importance sampling by the balance heuristic with r(00:11 latitude) from r_hat.csv); prior track = run J waypoint route sampler; 00:19 data option as labelled, log-on cause q = 1/3 with 'other cause' silent, survival factor applied; provisional physics: round-3 descent laws, bank limit U[52, 90] deg, interim pitch-down, uncontrolled arm uncalibrated (Boeing gate failed); no search, ocean-drift or other evidence applied (impact level); waypoints stratum only (core prior share 0.998). Error bars: 95 % seed-bootstrap intervals (2,000 draws; the 24 run J and the 16 supplement replicates resampled separately).
