Published hydrophone records read back from the figures: times and levels agree across sources

Simplified English: We read the traces from the published figures. In (a) and (b) three papers show the same explosion; the times agree to 3 s, and the peak in Kadri's figure agrees with the level that Vergoz printed to within 1 dB at Ascension and 1.5 dB at Crozet. In (c) we compare a published trace with our own processing of the same recording; the peaks agree to 0.7 dB and 2.4 s. These are published data read from figures, not new measurements.

Technical: (a,b) ARA San Juan calibration charge, 1 Dec 2017, 108 kg TNT (Vergoz et al. 2021 p. 2528). Kadri 2024 Fig. 8 (PMC raster 749 px; frame = axis limits): peak 3.44 Pa (130.7 dB re 1 uPa) at H10N, 1.06 Pa (120.5 dB) at H04S, vs Vergoz printed 130 / 122 dB re 1 uPa (p. 2529-2530). Vergoz Fig. 2 and Nielsen Fig. 3 carry no pressure scale: drawn as normalised envelope x printed peak, offset. H10N peak times 21:12:06 (Kadri), 21:12:04 (Vergoz), 21:12:03-06 (Nielsen, nodes 1-3). (c) CMST 2014-30 Fig. 1 vs IMOS 3315 file 531A728A.DAT (role B): Curtin gain file, -197.8 dB re V^2/uPa^2, logger clock -25.82 s (pre-registered clock test), 4th-order zero-phase Butterworth 1-120 Hz, column envelope on CMST's 0.69 s pixel grid; in 5-40 Hz the peak is -2.0 dB. (d) level in dB relative to each panel's maximum; CMST Fig. 2: jet colour scale inverted to dB (-40 to 0 re panel maximum), 5-40 Hz mean, 5-column running mean; CMST text 01:34:50 +/- 3 s. Scripts prepare/digitise_waveform_rasters.py and cmst_fig1_imos_overlay.py, module commit 5230679. Digitised published data; nothing here is a likelihood.
