The modelled sound channel gives an arrival as short as the measured F-35A arrival, whatever the source duration

(i) The grey lines are the sound of the F-35A crash, measured at Wake Island 3,250-3,340 km away and copied from the published chart. The blue lines are the sound that our model sends along the same path. The model gives the same short sound for a short and a long source, so this sound cannot tell how long the source was.

(ii) Measured: Metz et al. Fig. 3C/D, 1 s RMS 4-64 Hz, noise-subtracted, peak-aligned (DIGITISED, vector). Model: KRAKEN coherent 2-70 Hz on the range-independent WOA23 B5C2 April midpoint profile, flat bottom 5681/5646 m, source 10 m, receiver at the triad depth; module one-pole source; same 1 s RMS processing. Pre-registered tau scan (prereg 7dc315f): rms misfit flat within 0.4 dB over 0.05-10 s, tau not identified; -6 dB widths model 2.7/2.3 s vs measured 3.4/2.3 s. Range-independent profile is a declared reach gap. Caveats C1 (propagation slope) and C2 (coupling not calibrated for an airliner) apply. All F-35A data DIGITISED from Metz, Obana & Fukao (2023, Pure Appl. Geophys. 180:1343).
