
(i) We added our modelled sound loss to the sound measured at Wake Island in each frequency band. This gives the sound at the crash site. Its slope is inside the range that our impact model can make, so our sound-loss model does not add a wrong slope for this source near the surface. This is one crash and one model, so it is not a proof.

(ii) TL recalibration route 2 (tl_recal_block9 pre-registration, data source substituted by Metz Fig. 3A/B; prereg 7dc315f). S_F35,b = RL_b + TL_b, RL_b = noise-subtracted band excess from the colour-inverted spectrogram (80 dB floor), bands with arrival - noise >= 3 dB (16/20 Hz excluded at H11S1, 20 Hz at H11N1), TL = results-data/f35a_cal/f35a_tl.csv z_s 10 m. Module envelope of OLS slopes over tau 0.05-10 s, f^-2 and f^-4: -9.0 to +1.2 dB/oct; verdict CONSISTENT at both elements and under the new TL (-6.0 to -7.3 dB/oct). DESCRIPTIVE. Caveats C1 (propagation slope) and C2 (coupling not calibrated for an airliner) apply. All F-35A data DIGITISED from Metz, Obana & Fukao (2023, Pure Appl. Geophys. 180:1343).
