

Predicted against measured transmission loss for the 2001 air9 airgun shots

a

Cape Leeuwin (H01W), 1,663 km

b

Diego Garcia South (H08S), 3,549 km

What the chart shows: how much sound is lost between the air9 airgun site and two listening stations. The grey line is what Blackman et al. measured in 2001; the dots are what our propagation model predicts for the same path. Close agreement means the model is right about how far sound carries from this region. A loss chart cannot test how much sound an aircraft impact makes.

Technical: Blackman et al. 2004, UCRL-TR-207323, Fig. 23 (p. 21), air9 curve digitised (artifact 99b55187; ± 2 dB chart reading); KRAKEN adiabatic, hard bottom (cp 1,650 m/s, p 1.9, 0.5 dB/ λ), Francois-Garrison, WOA23/GEBCO 2026 path; residuals and verdict from hydroacoustics-blackman-validation.md (pre-registered rule); band = ± 7.9 dB. air8 (blocked to H01W, observed at H08S): control followed (+38.1 dB) and consistent (+0.1 dB).
