
(i) Plain language. The lines show the sound level at the two Wake Island stations. The blue band is the time when sound from the aircraft would arrive. The orange band is the time that an earlier study marked. In the blue band the level does not increase more than in quiet periods. In the orange band there are two short sounds. They come from the south-south-east (dots near 150°), not from the direction of the aircraft (dashed lines). The south station got them first. Sound from the aircraft gets to the north station first. The regular peaks at the north station come every 20 s from a different source; we did not examine them.
(ii) Technical. IMS H11N1-3/H11S1-3 EDH 250 Hz (EarthScope FDSN); StationXML response removed (pre-filter 1/2/110/120 Hz); 5-40 Hz 4-pole zero-phase; triad-mean 1-s RMS. Source NTSB DCA21FA174: 11:45:17 UTC, 21.27616 N 158.02565 W; c = 1.482 ± 0.006 km/s; predicted window ±45 s (pre-registered). p = matched filter (F-35A raw-record envelope, module M1b) against 1,240-1,250 background 90-s windows (14 adjacent days and event day), floor 1/(n+1) ≈ 0.0008. Panel c: 8-s frames, triad coherence above the event-day 99th percentile, apparent speed 1.3-1.7 km/s; dot size ~ coherence. Inter-triad lag of the two pulses +72/+73 s (north after south); a plane wave from 152.6° predicts +74.5 s, the ditching site -29.7 s. No propagation model used. Non-detection carries limited power (Fig. 2).
