
Plain: Each point compares how well the searches agree with an impact near the bearing crossing and with an impact anywhere else in the result. Above zero, the search supports the crossing. The seabed search supports it because most other positions were searched and nothing was found. The surface search goes against it. Open points have too few samples to be reliable.

Technical: run J, 4 strata by core P(family), q=1/3 (C2 silent). Locality rows weighted by the pre-registered acoustic likelihood (core sigma_b 0.5 deg); complement = run J outside the bearing strip. Seabed: L = rho + (1-rho) prod(1 - q c f), ATSB Phase 2 q 0.945, Bluefin-21 q 0.9, OI 2018 q 0.9 f 0.889 and OI 2025-26 q 0.9 f 0.7808 (inferred, grade C), impact point, reference rho 0.05; range rho 0-0.5 and ATSB only. Surface: CSIRO POD 1.0/0.15, windage 0.5 % on GlobCurrent 0 m, floor 0; range windage 0.5-2.5 %, POD field/item, floor 0-0.2. Physics not calibrated.
