
Change in the mean impact latitude on the 7th arc caused by the drift evidence (degrees; positive is north). Upper group: the drift model changed one step at a time, from the model as first scored to the headline model. Lower group: changes to the headline model. Grey band: half the difference between the two independent halves of the particles (+0.74 and +1.04 degrees) about the headline value, an indication of the Monte Carlo uncertainty. The mean with the satellite and flight data only is 36.72 degrees south.
