On the digitised H01W traces only the envelope matched filter reaches p = 0.05 inside an author's box (text time 00:52:03);
the four panel (a) boxes stay above p = 0.08 for every method

(i) Top row: Kadri's published pressure traces, redrawn from the figure's vector data (a decimated plot, not the recording). Lower rows: for each method, how unusual the statistic is against 14 days of real sea noise, as a probability (lower = more unusual; lines at 0.3, 0.1, 0.05). Orange bands: the author's boxes - text time 00:52:03, caption time 00:54:30, and the four 'weak' boxes of the 2025 poster panel (a). Chance alone gives about one value below 0.05 per 20 minutes of trace per method.

(ii) Prereg 78c7e88 (test set b). Traces: PDF vector polylines ~14.5 vertices/s resampled to 20 Hz, band 1-9 Hz. Null: IMOS 3376 background through a plot-decimation emulator (per 69 ms bin min and max vertices, 20 Hz), 1,344 files x 4 windows of 60 s. p = fraction of null window maxima >= statistic (floor 1/(2 n)). Matched filter uses the KRAKEN 2,200 km template envelope only. Digitised data; caveats C1, C2; H08S panels d, e in the results note (shot-dominated).
