

What the chart shows: (a) when the aircraft hit the water, under four ways of using the last satellite data. (b) the impact times that the three published Cape Leeuwin trace panels and the two Diego Garcia panels could show, for an impact at each latitude along the arc. Where the coloured bands do not cover the impact-time lines, the published traces could not show the impact even if it were loud enough. The chart says nothing about loudness (caveats C1, C2).

Technical: run J + northern supplement, p = 0.5; EoF total q = 1/3 (C2 silent) weights, survival factor, strata by p_core x Zhat. Arc proxy = weighted mean impact longitude per 0.5 deg latitude bin (production + supplement, D0', p = 0.5); bands = panel span minus geodesic / c with c = 1.482 +/- 2 x 0.006 km/s. Fig. 9 panels a-c 00:27-00:57 (H01W), d-e 01:00-01:20 (H08S), spans read from the digitised traces (metadata.json of the figure extraction). Grey above 20 S: outside the declared latitude span. PREDICTIVE, NOT CALIBRATED; C1, C2. prereg bc99b07.
