Of 165 candidate-receiver cells, 80 hold no recording; in 17 cells a held recording should have shown the candidate and shows nothing

Rows: the strongest two-site pair, then the five highest-ranked pairs and five highest-ranked single-site signals (ranking by likelihood ratio). Columns: every receiver. Cell: data held in the predicted arrival window, the largest matched-filter p (or Royer spectrogram peak) in it, and the expected level (dB above the background median) at the coupling the candidate needs.

No recording held
Held: candidate too weak to see there; nothing
Held: should have seen (detection probability >= 0.5); nothing
Held: the defining signal, or another row at p <= 0.05, is present
Held: not scorable (no level model or record edge); nothing
Held (Royer only): Royer marks an arrival in the window

(i) Each row is one candidate sound; the first row is the strongest pair named in the summary. Each column is one receiver. A grey cell means that we hold no recording for the time when the sound would arrive. A purple cell means that we hold a recording, the model says the receiver should have detected the candidate, and the recording shows nothing. The strongest pair (row 1) has two such cells: Perth Canyon 3376 and Portland 3274. The Cape Leeuwin signal of that pair is at the time of an arrival that Royer marks for his event A, an ice-quake far to the south. Digitised means copied from a published figure. These are model predictions; the sound-loss model and the coupling are not calibrated.

(ii) Source posterior = run J (search-geometry sample: waypoints stratum seeds 1-8 + northern supplement, 00:19 Held Out, p 0.5). Pairs: arc lag locus (offset 0), MC n 4,000, c ~ N(1.482, 0.006) km/s, pick sd 3.6 s; singles: sample conditioned on the arrival. Window = 2.5-97.5 % predicted arrival. p = M1b window-maximum p vs own-logger 1-15 Mar null (3315<-3376, 3275<-3274; panels: 3376 via plot emulator), not trials-corrected (CSV gives the corrected value). Expected level = peak 1 s 5-40 Hz SNR at the coupling eta for P_D = 0.5 at the defining receiver(s) (jointly for pairs), or eta 0.01 where eta is undefined; IMOS TL = RAM-corrected arc table; IMS = proxy noise, +4.8 dB triad gain; P_D = block 7 logistic, alpha 0.05. Strongest pair: locus 33.6 S 94.5 E, impact 00:31:41, eta 0.069 = 330x F-35A 2.1e-4 (composition v2); bearing from H01W 268.9 deg vs Kadri 57 / 306.18 deg (none within 37 deg; nearest Table 1 bearing 00:52:50 at 274.84 deg, 46 s later). Royer event A pick bar at H01W-2 on his Fig. 4: 00:51:56.8-00:52:04.5 (Table 5: 00:51:41-43; table-figure offset 13.6-16 s unresolved). Kadri times: text time 00:52:03, caption time 00:54:30. Defining rows at Perth Canyon 3315 in pairs 2-4 are band-energy 2-5 Hz rows (below the 8 Hz hardware corner); the matched filter there shows nothing, so they read 'should have seen'. Scott Reef 3250 and Portland from north of ~29 S: path blocked in the TL grid. PREDICTIVE, NOT CALIBRATED; C1 (slope misfit +10.4/+7.4 dB/oct at H01W/H08S), C2 (coupling not calibrated).
