

Simple summary: The curves show where the aircraft entered the sea, along the 7th arc. The satellite and flight data give the black curve. The debris finds move it a little north. One engine cowling found at Mossel Bay causes almost all of that move. The flaperon alone does not move it. No debris was found in Australia. That moves the curve further north, by an amount that depends on how likely people on Australian beaches were to find and report debris, compared with the African and island coasts.

Technical: run J impact samples, end-of-flight families pooled, 00:19 data held out; drift likelihood ln L = ln mean over ocean environments (32 south of 33.25 S, 16 north) x 256 detection-level draws of sum over finds of [ln(a.nu) - ln(A.nu)]; 84 release points 20-40 S on the run J median track and +/-50 NM; 6,250 particles per class per environment; GLORYS12 and GlobCurrent (product-relative windage) with ERA5 wind, equal weight in likelihood; 50 km find kernel; nine confirmed or almost-certain finds; Australian tiers city+inner = ratio, outer regional = 0.3 x ratio, remote = 0 (17 Oct ruling, ratio is a sensitivity); provisional windage, delay and level priors; no Bayes factor implied; coefficient jobs 91ee26ce and 272016f7, offline scorer validated against the module to 1.3e-6.
