

Like-for-like with the prior work's 'residual origin density': flat prior over 85-103 E, 43-25 S (no flight posterior), Pléiades x all four COSMO contacts (joint product, not the prior work's 50:50 pool; the pool is in closeup-stats.csv). Search factor: the searched-areas module's $\ln P(\text{no find})$ evaluated at every grid centre (point target, $\rho = 0.05$; shared miss dependence as in its run.toml).

Ocean models GLORYS12 + ERA5 and GlobCurrent daily + ERA5 at equal weight (the prior work: BRAN2016, OSCAR v2, GLORYS12 + WAVERYS); measured transport error; COSMO passes dawn-20 / dusk-21 Mar equally weighted (the prior work: 21 March). Outlines and grades as in the close-up figure.

No flight posterior, so no 00:19 option applies here. GlobCurrent daily label provisional (P4). Conditional on H; no Bayes factor or $P(H | \text{data})$. The grid-cell mode sits on a broad plateau (L_P and L_{C4} within 5 % of their local maximum over ~ 0.15 deg), so read the HDR, not the star.
