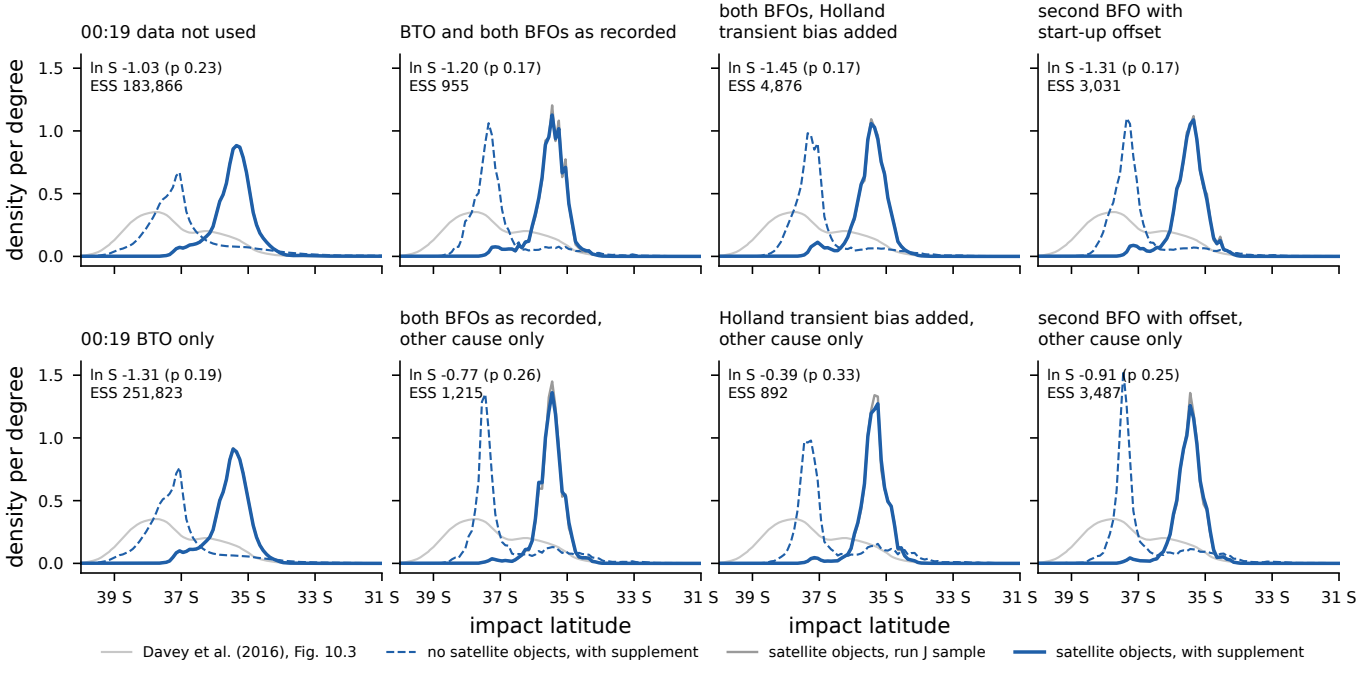
Under the satellite-object hypothesis the impact latitude moves to about 35.5 S for every treatment; adding the northern supplement does not change the conditional curve (both causes, 1/3 other, unless stated)



Footnote (simple): The data is conditional on the hypothesis that one or more objects seen by satellite on 20-23 March 2014 came from the aircraft. We do not use the shape of the objects. The end of flight physics is provisional. No seabed search is applied. All descent families are included. The grey line is the published reference curve. ln S is the tension between the flight data and the hypothesis; ESS is the effective impacts under the hypothesis.

Footnote (technical): Core run J (split-half accepted as a pass by project ruling, 16 Oct 2026), waypoints stratum; rule B over 2,399,999 run J and 1,600,003 supplement hand-off rows (r_hat from core), extra descents 64:256 (D2-D5). ln S, p: module tension (Handley-Lemos) of the flight-only 0.05 deg map against the H surface. Davey et al. (2016) Fig. 10.3 BTO+BFO, recovered from the PDF vector paths. Impact latitude in 0.1 deg bins. H: Pleiades rating 5 + COSMO-SkyMed F1-F4; rho 0.25; two ocean models. No identity likelihood; no Bayes factor or P(H). Before any seabed search.
