

MH370 known-flight WSPR arc-time windows

PHaRLAP-filtered raw clusters before control subtraction: common-aircraft-altitude propagation screen

Blind, epoch-partitioned selection; 25 km clustering, ≥ 3 independent links. These are all PHaRLAP-screened clusters in the central arc-time window before the ± 60 -minute controls are subtracted. Distance is to the static aircraft position at the BTO epoch and is descriptive, not a time-aligned recovery score for clusters from other WSPR slots. Truth and the joined report track were added only after selection. Latitude limits are symmetric about truth; pale-grey bands are outside the frozen candidate-search latitude. The ruler is a north/south great-circle distance. All retained raw clusters have 3 independent links.

Each marker is a spatially collapsed event with retained source altitude slices. Marker size encodes feasible-set midrange, not evidential strength; the audit CSV retains the source IDs.
