PHaRLAP-filtered residuals: common-aircraft-altitude propagation screen

Seven trajectory-blind BTO-arc searches; 25 km clustering, 25 km symmetric residualization and ≥ 3 independent links. A cluster remains only when neither of the other time panels has a cluster within the residual tolerance. Only residual centres are drawn; panel annotations retain the raw counts. No post-18:22 aircraft truth or trajectory was supplied or overlaid. A PHaRLAP-feasible mode is a propagation screen, not evidence that the mode occurred. Adjacent radio windows overlap, so cross-epoch counts are descriptive. Source altitude slices were matched across either control at any height before surviving co-located slices were collapsed for display; marker size encodes feasible-altitude midrange, not evidential strength.

— BTO arc at 10 km • Feasible-altitude midpoint 0.5 km • Feasible-altitude midpoint 6.75 km • Feasible-altitude midpoint 13 km
