

Pléiades-conditioned forward-transport source compatibility
BRAN2016, OSCAR v2 Final, and GLORYS12-WAVERYS alternatives with a declared equal-prior mixture; conditional on an equal-weight rating-5 object-location mixture

Shading and contours are normalized two-dimensional source-cell density; no transverse display width was added. The three transport families differ materially (pairwise total variation 0.484–0.570; mode separation 53.8–94.4 km). The final panel is their declared equal-prior mixture; the families are never multiplied as independent evidence and their spread is not treated as sampling error. This is transport compatibility, not an object-attribution result or a calibrated crash posterior.

RNZAF-labelled image GPS metadata in Pléiades geographic context 59 distinct reported positions from 132 georeferenced image records

User-supplied workbook labelled RNZAF: 132 of 183 records contain coordinates, representing 59 distinct reported GPS positions; six records require an explicit paired hemisphere-suffix correction and 51 lack coordinates. Marker area indicates image count at an identical coordinate. Points are display context only—not image footprints, searched-area coverage, non-detection evidence, debris observations, or an estimator likelihood. Datum, timezone, altitude, camera geometry, search outcome, and dataset completeness are unspecified.
