

MH370 Resolution

Final milestone - decision summary

The working region remains **34-36 degrees S, emphasizing roughly 35 degrees S near the seventh-arc corridor**. This is a provisional synthesis, not an exact coordinate, a calibrated probability distribution, or a demonstrated maximum after all searches.

Why this region

The retained case combines published satellite/flight feasibility with debris drift and surface-search evidence. Those analyses share data and assumptions; overlapping conditional hypotheses are not independent votes. Recent search coverage is still too poorly resolved to compute the residual optimum.

What to search next

Completing the official **7,428.54 km2 remainder** is a practical candidate, **not a demonstrated scientific optimum**. The remaining 71.46 km2 of a 7,500 km2 budget stays unallocated until validated gaps, contacts or changed-aspect repeat opportunities can be ranked. The northwest proposal sketch is not established as that remainder. No operational polygon is supplied.

Most important correction

The earlier 94% legacy detection rating is an area-weighted calculation. It cannot be applied to every searched cell. Under the report-assigned categories, nominal miss likelihood is 5% for a high-confidence cell, 30% for a lower-confidence cell and 100% for a gap. Actual location and detection weights remain uncalibrated.

What changed since the first milestone

The search recommendation is more qualified; public geometry and negative-search pitfalls are better diagnosed; the fuel-bridge implementation has progressed; and a conditional Pléiades/IGOGU atlas is now integrated. The broad working region has not changed.

What the new evidence does - and does not - show

Conditional geographic overlap

The equal-weight BRAN2016, OSCAR and GLORYS12/WAVERYS mixture peaks near **35.22 S, 92.25 E**, conditional on the photographed-object hypothesis and specified drift assumptions. About 5.4% of that model mass is inside the northwest sketch and 2.4% inside the southeast sketch. These are not calibrated wreckage probabilities.

The recovered IGOGU measure includes 119,088 draws in the mixture's 90% region after an assumed continuation to 00:19 and an R600 sensitivity gate. Their effective sample size is only about 77. No tested gated 00:19 position lies within either proposal sketch; that does not exclude a later impact there. The paths are not validated impact trajectories.

Estimator progress

Rerun checkpoint 19 has a feed-resolved powered fuel adapter that checks the 18:28 anchor without a reset. Its archived affected Rust log records 161 passing tests; five independent Python tests were rerun successfully for this synthesis. A full stochastic aircraft bridge and replacement geographic estimator remain unvalidated.

Research priorities

1. Obtain authoritative AUV coverage, quality masks, contract boundaries and contact dispositions.
2. Finish and validate the stochastic aircraft bridge; reconcile canonical satellite bursts, shared calibration and radar provenance.
3. Validate a separate end-of-flight model, then test hydroacoustic A/E/F attribution and CL/DG arrival predictions with blind controls.
4. Calibrate drift and repeat-search detection before optimizing the 7,500 km² allocation.

Completed work and limitations

This final synthesis verified the initial archive hash, assembled 21 dependency archives, checked 213 Rerun source-manifest entries, replayed five Python tests and passed 12 new exact arithmetic controls. No new physical particle-filter or impact simulation was run. This is not a claim of 18 hours of uninterrupted computation. The A/E/F chart and validated impact/acoustic PDF remain outstanding.
